

## Identity and Access Architecture Landscape

### Overview

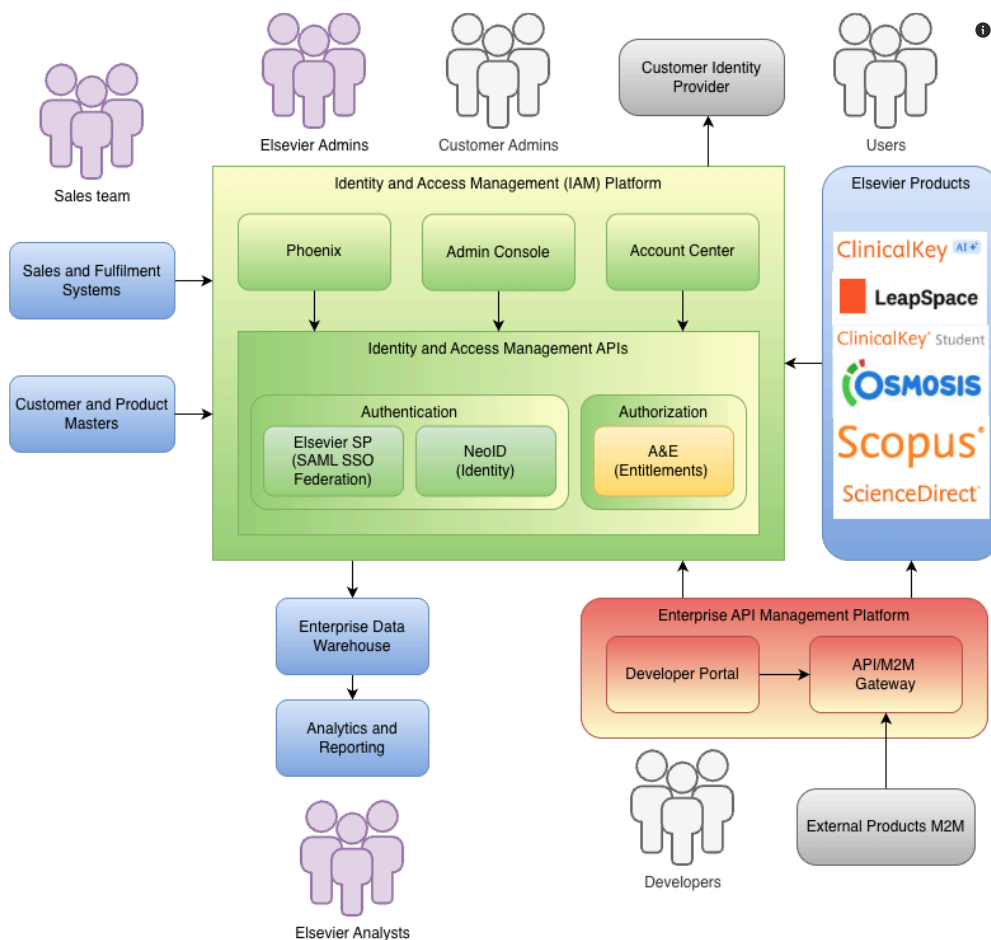

This page gives a high level overview of the current target architecture, which is then broken down further into the capability levels for a more detailed view of the current and target landscapes

- [Capability - Authentication](#)
- [Capability - Authorization](#)
- [Capability - Identity and Access Configuration and Reporting](#)

Please contact [@Stephen Brewell](#) [@Kyle Herock](#) [@Avik Aggarwal](#) for any questions

### Architecture System Landscape

The diagram below gives a “marketecture” view of the current view of the Identity and Access architecture

### Notes

- The Identity and Access Management Platform (aka IAM Platform, IAMP, [IAM Platform Service Overview](#))
  - Is a collection of systems that provide authentication, authorization and entitlement services to Elsevier's products, and includes
    - ID+ and NeoID (Auth0) for authentication of users and federation to external identity providers as required
    - NeoID (Keycloak) for Role Based Access Control provision - it provides a common authorization interface to Products irrespective of how the users of them were authenticated
    - A&E for content and product based entitlements
- The IAM Platform APIs are based on a conceptual data model ([Conceptual Data Model 1.3](#)) that abstracts away the individual representations of identity and access data in the underlying systems and presents a common interface to the applications that consume

them, performing any required routing, transformation and business logic to support search and query access to the underlying operational data stores

- Consumers of the IAM Platform APIs include
  - Phoenix: a replacement for Chief as the Elsevier administration console for IAM data
  - Admin Console: the customer facing console for administration of IAM data, replacing Admin Tool and other customer facing consoles
  - Account Center (currently MyAccount): the individual user-facing console for managing profile, preference, privacy and entitlement data
  - Sales systems: such as the eCommerce platform for B2C purchases and Salesforce for B2B license deals
    - Strategy is to automate the current manual fulfilment processes
  - Accepting updates from Product and Customer masters to reflect in entitlement stores and consoles.
- Both ID+ and NeoID provide OIDC/OAuth2 compliant interfaces to the products that use them (replacing the legacy A&E API based authentication still used by some Elsevier products)
  - There are many products in Elsevier that have their own identity stores; the strategy is to consolidate these into a single identity provider over time
    - The target state would also see the removal of ID+ from this architecture, leaving just NeoID as the single strategic identity provider.
  - The target is for new Elsevier products or acquisitions to utilise NeoID, as this is where all new development to support modern identity and access controls will be focussed
- The target for analytics use cases is to export the data from the IAM Platform systems into the Elsevier data warehouse in Snowflake, catalogue them in Colibra and use common reporting tools such as Tableau, joining these identity and access datasets with other Elsevier-wide datasets present as required

## Detailed View

A more detailed view of the above is shown below
